# Babylonian Mathematics, Analog Computation, and Lunar Surface Impact Speed 

## 1 Introduction

For this project, a combination of ancient mathematics and modern electronics will be used to estimate the impact speed of an object released from rest at various heights (not to exceed 6 meters) above the surface of the moon.

On page 4 , Square roots are displayed in table 1 and impact speeds are displayed in table 2.

## 2 Mathematical modeling

First, a brief outline of the Babylonian method to extract the non-negative square root of a number using three iterations:

Let $R^{2}=N$, such that $L<N<H$, where $L$ is the perfect square just less than $N$, and H is the perfect square just greater than N .

Assume that $R_{L}$ is the square root of $L$ and $R_{H}$ is the square root of $H$, then a $\mathrm{R}_{\mathrm{H}}=\mathrm{R}_{\mathrm{L}}+1$.
$1^{\text {st }}$ iteration:

$$
\mathrm{R}_{1}=\left(\mathrm{R}_{\mathrm{L}}+\mathrm{R}_{\mathrm{H}}\right) / 2=\left(\mathrm{R}_{\mathrm{L}}+\mathrm{R}_{\mathrm{L}}+1\right) / 2=\mathrm{R}_{\mathrm{L}}+1 / 2
$$

$2^{\text {nd }}$ iteration:

$$
\mathrm{R}_{2}=\mathrm{N} / \mathrm{R}_{1}=\mathrm{N} /\left(\mathrm{R}_{\mathrm{L}}+1 / 2\right) .
$$

$3^{\text {rd }}$ iteration:

$$
\mathrm{R}_{3}=\left(\mathrm{R}_{1}+\mathrm{R}_{2}\right) / 2=\left[\mathrm{R}_{\mathrm{L}}+1 / 2+\mathrm{N} /\left(\mathrm{R}_{\mathrm{L}}+1 / 2\right)\right] / 2 .
$$

From elementary physics, $\mathrm{v}=\sqrt{ }(2 \mathrm{gh})$ (when drag is negligible), where $\mathrm{g}=$ $1.625 \mathrm{~m} / \mathrm{s}^{2}$ (value at the lunar surface) and $\mathrm{h}=\mathrm{N}$ (in meters).

Simplifying, $\mathrm{v}=\sqrt{ }\left(2 \times 1.625 \mathrm{~m} / \mathrm{s}^{2} \times \mathrm{N}\right) \cong 1.80 \times \mathrm{R}_{3}$.
